Dissecting aneurysm of middle cerebral artery following resection of meningioma

Sir: Dissecting aneurysms of the intracranial arteries are rare. Spontaneous dissecting aneurysms have been reported in patients with arterial hypertension, cystic media degeneration, fibromuscular dysplasia, and in cases of Marfan’s syndrome.12 Blunt skull trauma may also lead to defects of the internal elastic membrane of intracranial vessels, but there is always the possibility of preexisting vascular lesions.2 We present a case of post-traumatic dissecting aneurysm following partial resection of a large sphenoidal meningioma.

A 49 year old patient was admitted for the removal of a large meningioma. CT showed a tumour of the right sphenoid wing measuring 3.5 × 4 cm, with a 0.5 cm shift of the midline structures to the left. In preoperative angiography there was distension of the carotid siphon and the circle of Willis. The M1 sector of the ipsilateral middle cerebral artery was stenosed. At operation, the tumour was found surrounding the M1, M2, and M3 segment of the middle cerebral artery and the proximal segments of the anterior and communicans posterior arteries. Partial resection of the tumour was performed, leaving some surrounding the medial cerebral artery, which was seen pulsating during the operation. Twenty four hours after surgery, CT showed a slight hypodensity in the right temporal lobe. Three days after operation a large infarct in the area of the right middle cerebral artery was diagnosed by CT. The patient died on day 6 after surgery.

A large, approximately 5 day old infarct of the middle cerebral artery was found at postmortem examination. Small tumour fragments were still attached to the vessel wall. Histologically, an endotheliomatous meningioma had invaded the wall of the middle cerebral artery. There were multiple ruptures of the internal elastic membrane along a 5 mm segment, with underlying haematomata (fig). Some granulation tissue and iron-positive macrophages at the border of the haematomata were found. The other arteries were free of degenerative changes.

Some cases of dissecting aneurysms of intracranial arteries had recent head trauma, in other cases a generalised vasculopathy was observed.14 In our case, this was clearly absent; all other vessels were free of pathological changes. The resection of a tumour intimately connected to the vessel wall appears to be the only plausible explanation for this dissecting aneurysm. In one previous case1 a dissecting aneurysm was considered to be directly related to surgery and occurred after resection of an aneurysm of the middle cerebral artery. This is the first instance reported after surgery for a brain tumour.
