Spontaneous basilar artery dissection: contribution of magnetic resonance imaging to diagnosis

Right vertebral angiography and axial T1 weighted MRI in a 53 year old man presenting with spontaneous isolated mesencephalic subarachnoid haemorrhage. Clinical outcome under conservative treatment was satisfactory.

On admission, left:
Top—upper half of the basilar artery is narrowed, suggesting either spasm or dissecting aneurysm.
Bottom—MRI shows a wall haematoma in the midpoint of the basilar artery, surrounding an eccentric narrowed lumen, suggesting an isolated basilar artery dissection.

Two months later, right:
Top—normal basilar artery.
Bottom—intramural haematoma has spontaneously resolved; basilar artery lumen is of normal diameter.

It is important to perform an MRI in mesencephalic subarachnoid haemorrhage to detect basilar artery dissection.
