public. We can, at any rate, conclude that these pages make stimulating and suggestive reading. The author's enthusiasm and sincerity are highly persuasive and no student of human nature can afford to neglect his interesting views.

As a token of appreciation and gratitude on the completion of 35 years of scientific teaching and research this volume is dedicated to the distinguished neurologist Professor Edward Flatau by a number of colleagues and friends, Polish and otherwise. Nearly all the contributions are written in that language, but some are in French or German, and three in English. Numbering 68 in all, they include many of considerable originality and value, and form a useful addition to a neurological library.

There is no authority who can deal with psychiatry more lucidly and interestingly than Dr. William White. These twelve lectures to medical students who are on the threshold of the study of mental medicine are a model of how the subject-matter should be presented. The logical order in which the material is given is satisfying to the mind. Its contents are ideally set forth for the budding student and should prove useful to any reader who desires a rational concept of the psychoses.

This small volume is an addition to the well-known "Students' Aids Series." The aim of the book is to offer a means of rapid revision following a study of the larger textbooks on the subject, and to emphasize those points useful to students studying for a diploma in psychological medicine. Though psychology does not easily lend itself to such treatment, the writer has well fulfilled these objects. We might draw attention to faults of omission and commission, but considering the difficulty of such a compilation it is perhaps surprising that there are not more. Delusions are not mentioned, nor is the psychopathology of hallucinations referred to. It is nevertheless a useful addition to the series.
