Short report

Radiculopathy as a complication of ankylosing spondylitis

W. J. K. CUMMING, AND M. SAUNDERS

From the Department of Neurology, Middlesbrough General Hospital, Middlesbrough

SUMMARY A cauda equina syndrome in association with ankylosing spondylitis is well recorded. We report the occurrence of an upper limb radiculopathy which progressed to a cauda equina syndrome in association with ankylosing spondylitis.

Neurological complications of ankylosing spondylitis are uncommon and have recently been reviewed (Thomas *et al.*, 1974). We report the occurrence of an upper limb radiculopathy occurring in association with ankylosing spondylitis.

Case report

The patient (A47966) was well until 1964 when, at the age of 35 years, he developed progressive pain and stiffness in his lower back, noticeable particularly in the early morning. A diagnosis of ankylosing spondylitis was made. Over the next four years, the pain and limitation of back movement spread to the dorsal and cervical regions. In 1970, because of severe pain, he was treated with deep x-ray therapy. Twelve hundred rads were given to each of the cervical, dorsal, lumbar, and sacroiliac regions over a 10 day period. This was followed by marked symptomatic relief. In 1971 he had bilateral costoclavicular pain which was again treated with deep radiation (700 rads as a single dose).

In 1972, at age 43 years, 11 months after the last course of deep x-ray therapy, he noticed numbness involving the lateral three fingers of the left hand. Over a four month period the numbness spread to involve the ulnar border of the forearm and all of the hand. Examination confirmed sensory loss to all modalities from C6 to T1 dermatomes on the left. There was mild (MRC grade 4) weakness of grip of the left hand. All deep tendon reflexes were elicitable with reinforcement. The

rest of the neurological examination was normal. There was limitation of back movement with local tenderness over the sacroiliac joints. Radiology of the cervical, dorsal, and lumbar spine confirmed the ankylosing spondylitis. A myelogram was normal.

The patient was lost to follow-up until January 1977. At that time he gave a history of progression of the sensory abnormalities to affect the ulnar border of the right arm and hand. Examination confirmed the previous sensory abnormalities in the left hand and showed progression of his motor weakness to MRC grade 3. There was sensory loss in the C7/8 dermatomes on the right. All the deep tendon reflexes were now absent and the rest of the examination was normal. Neurophysiological studies were performed (Table) and showed evidence of involvement of all the sensory nerves in the upper limbs, the lesion being distal to or at the dorsal root ganglia. A repeat myelogram was normal, as was the CSF obtained at the time of

Table Nerve conduction velocities

Nerves	Latency (m/s)	Amplitude (μ V)	Velocity (m/s)
Motor			
Right median			
Wrist	3.6		
Elbow	7.6		55
Right ulnar			
Wrist	2.9		
Elbow	7.2		57
Right lateral popliteal			
Ankle	4.7		
Fibula	11.6		46
Sensory			
Right median	2.4	5	54
Right ulnar	NR		
Left median	NR		
Left ulnar	NR		

NR = no response.

Accepted 25 January 1978

the myelogram. In August 1977, the patient complained of progression of the sensory abnormality to the right leg, and examination confirmed L5 dermatome sensory loss.

Discussion

This patient had a slowly progressive, predominantly sensory radiculopathy which came on six years after the onset of his ankylosing spondylitis. Nerve root lesions in the presence of extensive bony abnormalities of the spine would not be unexpected, but no evidence of foraminal encroachment was demonstrated in this patient. Two patients with nonprogressive root lesions have been described by Thomas *et al.* (1974). We do not think that the radiotherapy given to our patient was the cause of his symptoms, since the cervical radiation dose was well within the accepted limits (Pallis *et al.*, 1961). Matthews (1968) and Hassan (1976) have described a cauda equina syndrome in association with ankylosing spondylitis, which has been shown to be caused by posteriorly situated diverticula of the lumbar theca. We believe that

two normal myelograms in our patient effectively negate this possibility in the cervical region in his case.

We believe that this patient is now developing the previously described cauda equina syndrome in association with ankylosing spondylitis. We would draw attention to the possibility that similar symptoms can arise from the cervical region and may be the presenting symptoms.
