Short report

Phenylacetic acid in human body fluids: high correlation between plasma and cerebrospinal fluid concentration values

SUMMARY In a group of six Parkinsonian patients and 13 "controls" with non-Parkinsonian neurological disease, there was a high correlation between both free and conjugated phenylacetic acid concentrations in plasma and cerebrospinal fluid taken at about the same time. This compound is the major metabolite of phenylethylamine, the production of which may be disturbed in a number of neuropsychiatric illnesses. Thus plasma measurements might be employed clinically to provide an estimate of central changes in phenylethylamine economy. A small but significantly higher proportion of conjugated phenylacetic acid was present in the plasma (but not cerebrospinal fluid) of Parkinsonians compared with controls.

Phenylacetic acid is the major metabolite of phenylethylamine, a "trace amine"¹ which has become the focus of considerable clinical attention in recent years. This amine has been invoked as a possible aetiological agent in the pathogenesis of certain disease states, including depressive illness,² schizophrenia,³ migraine⁴ and aggressive psychopathy.⁵ Because phenylethylamine itself is normally present in body fluids in very low concentration requiring extremely sensitive methods for its estimation which, by their nature, are exacting and prone to interference, phenylacetic acid assay has become accepted as a guide to the production of its parent monoamine. Like phenylethylamine, unconjugated phenylacetic acid is a lipid-soluble relatively non-polar compound which might be expected to penetrate cell-membrane barriers with some facility. However, in the cat at least, the ¹⁴C-labelled acid is only able to cross the blood-brain barrier with difficulty.⁶ In man, this acid is excreted mainly as its glutamine conjugate⁷ which is much more polar and less lipid soluble than the free acid. Thus, little communication might have

been expected between plasma and cerebrospinal (CSF) compartments.

With clinical interest being predominantly centred on neuropsychiatric illness, it has been tacitly assumed that information about central phenylethylamine economy might most usefully be obtained by determining phenylacetic acid levels in the CSF.^{8,9} Where this has not been logistically feasible, however, plasma measurements have been performed.⁵ Although both approaches have yielded positive and distinctive findings, the relationship between the two groups of data remained unclear. We therefore decided to perform parallel studies on plasma and CSF samples drawn at about the same time to see whether we could identify any connexion between the two sets of values. Unexpectedly, we were able to identify a high degree of correlation not only between free phenylacetic acid values but also those of its glutamine conjugate.

Methods

Lumbar CSF and venous blood samples were drawn within 10 to 15 min of each other on in-patients at University College Hospital. The 13 "control" subjects (seven male, six female) were patients who had had CSF examinations performed as part of an investigation of peripheral neuropathy, radiculopathy or spinal cord

disease. Six Parkinsonians (five male, one female) were recent admissions who had not begun levodopa therapy at the time the samples were collected. Blood was taken into lithium heparin tubes; plasma was separated immediately and stored at -15°C to await analysis. CSF specimens were also stored at -15°C . Plasma and CSF concentrations of free and total (free + conjugated) phenylacetic acid were measured by gas chromatography-mass spectrometry using a selected ion monitoring procedure¹⁰ with slight modifications. $[\text{D}_5]$ phenylacetic acid was substituted for the $[\text{D}_7]$ isomer as internal standard in the estimation of free phenylacetic acid, and a mixture of $[\text{D}_5]$ phenylacetic acid plus $[\text{D}_5]$ phenylacetylglutamine (ratio 1:2 in CSF assay and 1:10 in plasma assay) was used, instead of $[\text{D}_7]$ phenylacetic acid, in the estimation of the total acid.

Results

Mean ($\pm$ SD) concentrations of free, conjugated and total phenylacetic acid in Parkinsonian and control plasma and CSF are shown in table 1. In both groups there were highly significant correlations between plasma and CSF concentrations of free, conjugated and total phenylacetic acid respectively. There was a small but significantly higher proportion of plasma (but not CSF) conjugated phenylacetic acid in Parkinsonians compared with controls (table 2).

Discussion

Although plasma concentrations of free acid were at

least five times higher than those of CSF and the plasma levels of conjugated phenylacetic acid exceeded those of CSF at least twelve-fold, CSF values in an individual changed sensitively in direct proportion to those of the corresponding plasma. It may thus be inferred that, had Sandler *et al* measured plasma phenylacetic acid concentrations in their depressive⁸ or schizophrenic⁹ series, they would respectively have been decreased or increased, in proportion to the CSF values obtained. Had it, conversely, been practicable to acquire CSF samples from the aggressive psychopaths⁵ they described, we may suppose that they would have followed the raised plasma values observed in these subjects.

Despite the general consensus that phenylacetic acid production mirrors that of endogenous phenylethylamine, findings have begun to emerge making a reassessment of this view timely: germ-free rats excrete only about one quarter as much total phenylacetic acid as conventional controls,¹¹ suggesting a sizeable contribution from the gut flora. However, the proportion of phenylacetic acid provided by gut flora (if these data can be extrapolated to man) may derive from some route of degradation different from that initiated by phenylalanine decarboxylation to phenylethylamine. Although the output of the latter is increased substantially in man following complete and irreversible inhibition of the phenylethylamine-preferring monoamine oxidase B by deprenyl,¹² the total is still only a

Table 1 Showing plasma and cerebrospinal fluid (CSF) concentrations of free and conjugated phenylacetic acid in Parkinsonian and control subjects

		Control subjects (n = 13)		Parkinsonians (n = 6)	
		Plasma	CSF	Plasma	CSF
Free phenylacetic acid (ng/ml)	Mean $\pm$ SD	161.8 $\pm$ 80.3	31.6 $\pm$ 23.6	105.7 $\pm$ 84.5	25.6 $\pm$ 15
	R		0.834		0.924
	p		< 0.001		< 0.01
Conj phenylacetic acid (ng/ml)	Mean $\pm$ SD	412.5 $\pm$ 247.9	29.7 $\pm$ 14.3	424.5 $\pm$ 339.3	20.2 $\pm$ 6.6
	R		0.900		0.922
	p		< 0.001		< 0.01
Total phenylacetic acid (ng/ml)	Mean $\pm$ SD	574.3 $\pm$ 316.9	61.3 $\pm$ 36.3	530.2 $\pm$ 419.7	45.8 $\pm$ 21
	R		0.962		0.970
	p		< 0.001		< 0.01

Table 2 Comparing plasma and cerebrospinal fluid (CSF) concentration of free phenylacetic acid expressed as a percentage of concentration of conjugated and free plus conjugated (total) acid in Parkinsonians and control subjects

		Plasma		CSF	
		Control subjects n = 13	Parkinsonians n = 6	Control subjects n = 13	Parkinsonians n = 6
Free as percentage conj phenylacetic acid	Mean $\pm$ SD	44.0 $\pm$ 17.2	25.8 $\pm$ 9.54	108.7 $\pm$ 56.5	118.3 $\pm$ 32.7
	t		2.40		NS
	p		< 0.05		
Free as percentage total phenylacetic acid	Mean $\pm$ SD	29.6 $\pm$ 7.61	20.2 $\pm$ 5.90	49.0 $\pm$ 13.0	58.4 $\pm$ 6.65
	t		2.69		NS
	p		< 0.02		

small fraction of the very large daily output of phenylacetic acid.⁷ Even though further information is required, however, before the full significance of changes in phenylacetic acid concentration in different clinical groups is clear, these findings can still be useful as state markers and employed accordingly, particularly for the purpose of defining subsets of particular diagnostic classifications. We should remember, too, that in clinical conditions associated with raised circulating concentrations of phenylacetic acid,^{5,13} the literature provides us with ample reason for suspecting that the compound may, under certain circumstances, be toxic in its own right.¹⁴⁻¹⁹

There was one further finding of interest which emerged from this investigation. A small but significantly higher proportion of plasma (but not CSF) phenylacetic acid in Parkinsonians compared with controls was present in conjugated form, thus providing yet another biochemical change to add to the list of systemic (as opposed to central) deficits of this disease. Whilst its significance remains unclear, it is reminiscent of an earlier finding of ours in Parkinson's disease²⁰ where we detected an increased basal urinary output of the (sulphate) conjugate of tyramine, another trace amine closely related to phenylethylamine. A more systematic study of conjugation mechanisms in general in this disease state might provide useful information.
