SUMMARY The numbers of neurons were counted in the ventral and dorsal anterior and ventral and dorsal posterior part of the putamen of 11 Huntington's disease and nine control patients. The process of neuronal cell loss in Huntington's disease proved to be unevenly spread throughout the putamen; the ventral anterior part was relatively spared as compared with the other parts of the putamen. A significantly higher number of neurons was found in the ventral part of the putamen in the controls.

The clinical and neuropathological findings in Huntington's disease are well-known.^{1,2} The main morphological abnormalities are found in the striatum and frontal cortex, although other parts of the central nervous system are involved as well.³ The microscopical findings consist of neuronal loss and astrogliosis, affecting the caudate nucleus and putamen equally. In coronal sections, only minor changes have been described in the ventral-anterior part of the striatum, where the caudate nucleus and putamen fuse.⁴ It has been proposed that the ventral part of the striatum, including the nucleus accumbens, plays a decisive part in the initiation of movements, activated by emotion, whereas the dorsal part of the striatum preferentially subserves cognitively activated movements.⁵ On such a basis, the ventral striatum is to be interpreted as a functional unit, without histological borders. Therefore, we investigated the ventral-anterior part of the putamen in Huntington's disease, in comparison to the dorsal and posterior parts of the putamen.

Material and methods

The brains of 11 patients with clinically, genetically and neuropathologically proven Huntington's disease and nine control patients were examined. The clinical data are summarised in tables 1 and 2. The Huntington's disease and control necropsies were performed within 6 and 24 hours after death, respectively. The brains were fixed in

phosphate-buffered formalin (4%), and were cut in frontal sections. Four putaminal areas, namely the ventral and dorsal parts in the anterior and posterior part were investigated (figs 1A and B).

The anterior part of the putamen was defined as its area anterior to a coronal plane through the anterior commissure. The posterior area of the putamen was defined as the area lying caudally to the plane through the anterior commissure, and lateral to the thalamus. In all areas, neurons were counted in 7 μ sections in 10 adjacent fields at a magnification of 400 $\times$ (surface area of 0.073 mm²). Only those neurons were counted that met the following criteria: the nucleus contained a nucleolus; the cytoplasm showed finely granular material and was clearly discernible from

Table 1 Clinical data of 11 patients with Huntington's disease

Huntington's disease:	11 cases (3 men and 8 women, including 1 juvenile)
Mean age at onset:	41.6 years (29-59 years; juvenile 7 yr)
Mean duration of illness:	10.6 years (5-15 years; juvenile 4 yr)
Mean age at death:	52 years (36-73 years; juvenile case 11 yr)
Cause of death:	suffocation
	bronchopneumonia } 11
Mean brain weight: (7 cases)	1060 g (780-1240 g)

Table 2 Clinical data of nine control patients

Control group	9 cases: 6 men and 3 women
Mean age at death :	68.4 years (53-86 years)
Cause of death :	cerebral haemorrhage :1
	subdural haematoma :1
	cerebral infarction :1
	cardiac arrest :2
	bronchopneumonia :2
	pulmonary emboli :1
	pleuritis carcinomatosa :1
Mean brain weight :	1310 g (1070-1520 g)

the neuropil. Dead neurons, immediately adjacent to vessels, and neurons that could not be identified with certainty were excluded from counting. No discrimination was made between large and small neurons. The cells were counted twice by two independent observers. The Student *t* test was used for the comparison between the groups, and between the anterior and posterior putaminal parts.

Results

The results are shown in table 3 and fig 2. The inter-rater and intra-rater variability was less than 5% each.

Marked neuronal loss, of course, was noted in the Huntington brains. In every area, the mean number of neurons differed significantly from the control

group ($p < 0.001$). The loss of neurons in the ventral anterior parts of the Huntington putamen was, however, significantly less marked ($p < 0.001$), as compared with the other three areas (fig 2). The mean number of neurons in the ventral anterior and ventral posterior parts of the control putamen was significantly higher as compared with the dorsal putaminal parts ($p < 0.01$ and $p < 0.05$ respectively). In fig 2 the differences between the areas are represented.

Discussion

The investigation of the normal striatal cytoarchitecture has led to different conclusions. Namba*

Table 3 Mean numbers of neurons of the areas studied in the ventral and dorsal part of the anterior and posterior part of the putamen in 11 Huntington's disease (HD) and 9 control patients (CO). The differences between the HD and CO and between the ventral and dorsal areas are given (Student *t*).

	anterior ventral	anterior dorsal		posterior ventral	posterior dorsal	
HD	145 $\pm$ 48	40 $\pm$ 21	$p < 0.001$	35 $\pm$ 15	35 $\pm$ 20	NS
CO	351 $\pm$ 30	289 $\pm$ 36	$p < 0.01$	342 $\pm$ 36	299 $\pm$ 31	$p < 0.05$
	$p < 0.001$	$p < 0.001$		$p < 0.001$	$p < 0.001$

described five layers with different cell densities in the caudate nucleus. The densities of large and small neurons appeared higher in the lateral part of the putamen and in the medial caudate nucleus, compared with the medial putamen and lateral caudate nucleus respectively.⁶⁻⁸ The normal striatal neuron density showed an increase in antero-posterior direction,⁸ which was not confirmed in our study. We found a higher neuron density in the ventral part of the putamen in controls.

Despite those reports, the striatum, including the nucleus accumbens, is still being regarded as a morphologically rather homogeneous structure. The reported ratios between its large and small neurons vary from 1:20⁹ to 1:270⁸. The divergence in ratios might be explained mainly by difference in counting methods and section thickness. A ratio of 1:140-160 is generally accepted.¹⁰

In Huntington's disease, the atrophy usually affects the caudate nucleus and the putamen equally.¹¹ The region where caudate nucleus and putamen fuse ventrally, however, shows only minor changes.⁴ The posterior part of the putamen usually shows degeneration comparable to the anterior dorsal part.^{7,12-15} The anterior part of the Huntington putamen is relatively less affected.¹⁶ Our study confirms the earlier unquantified findings. The ventral anterior part of the putamen is relatively spared, as compared with the dorsal anterior and posterior putamen. On the assumption that the initial numeri-

cal neuronal distribution in Huntington's putamen is identical to that of controls, an evenly spread process of cell death can not explain our findings in the Huntington putamen. Neuronal loss in the ventral posterior Huntington putamen seems to be more severe and in the ventral anterior part much less expressed, compared with the dorsal parts. These findings and the relative sparing of the nucleus accumbens^{17,18} support the hypothesis of the functional unity of the ventral striatum.

We thank Dr EA van der Velde (Dept of Medical Statistics), Prof Dr GW Bruyn for his critical remarks and Mrs I Harlaar-Kiela for typing the manuscript.
