mg/kg). Endotracheal intubation was performed during muscle relaxation with pancuronium (0.1 mg/kg). Anaesthesia was maintained with nitrous oxide, oxygen, and isoflurane (0.7–1.2%).

Case 1 was a 51 year old man who, since 1986, had had a progressive spastic paraparesis and who complained of cervicobrachial pain. Neuroradiological investigations showed cervical spondylosis with a narrow canal from C3 to C7. The patient underwent a C3–C7 posterior laminectomy. After operation he complained of weakness and paraesthesiae in both hands. Motor and sensory functions in the arms were restored after three to four weeks.

Before laminectomy, the potential recorded epidurally at Cv5 after median nerve stimulation was characterised by a normal P10 followed by an N11 wave with a peak latency of 12.3 ms, and an N13 wave at 13.9 ms. Amplitude (P10–N13: 12.8 μ V) and waveform were normal. After laminectomy, the disappearance of the N13 wave was noticed. The P10 and N11 waves were unchanged (figure).

Case 2 was a 56 year old man who presented in 1984 with progressive spastic tetraparesis and hypoaesthesia below C4. An MRI of the cervical spine showed spondylotic stenosis of the canal from C3 to C5. He underwent a C3–C5 posterior laminectomy. After operation, he showed a transient (seven days) decrease of motor performance in the distal segments of the arms.

Before laminectomy, the potential evoked by median nerve stimulation at Cv5 consisted of a slightly delayed P10 (peak latency: 11.2 ms), N11 (peak latency: 13.6 ms), N13 (latency: 14.9 ms), followed by a slow positive wave (P18 at 25.8 ms). Amplitude (P10–N13: 15 μ V) and waveform were normal. After laminectomy a decreased amplitude (P10–N13: 10.7 μ V) and a longer duration (11.8 ms *v* a prelamination value of 4 ms duration) of the main negative wave (N13) were evident (figure).

Case 3 was a 67 year old man with spastic tetraparesis and hypoaesthesia of both hands. Cervical MRI showed a multisegmental spondylosis from C4 to C7. The patient underwent a C3–C7 posterior laminectomy. After operation a transient (four weeks) increase of the paresis and hypoaesthesia of upper extremities was evident.

Before laminectomy, the epidural evoked potentials consisted of a slightly delayed P10 (peak latency 11.3 ms) followed by a negative wave peaking at 14 ms. The amplitude was normal from Th1 to Cv6 (P10–N13: 10 μ V), whereas it was decreased above Cv5–6 (P10–N13 at Cv5–6: 5 μ V). After laminectomy a decrease in amplitude or disappearance of the main negative wave (N13) was evident (figure).

In these three cases, laminectomy was followed by an alteration in the postsynaptic component (N13) of the median nerve evoked potential, whereas the root component (N11) was unchanged.² This is consistent with grey matter damage. The genesis of this damage is probably a vascular insult in an already hypoperfused area.^{3,4} Indeed, in cervical spondylotic myelopathy the osteophytic process may impinge on the anterior spinal artery and cause hypoperfusion with loss of the haemodynamic autoregulation in the spinal cord watershed areas.⁵ The decompression by posterior laminectomy may increase the blood supply, but as a consequence of the previously

mentioned loss of haemodynamic autoregulation, it may cause hyperaemia in these areas and induce the paradoxical effect of a further ischaemia. Other mechanisms of damage such as cervical spine instability, a local concussion of the cord, or a temporary oedema caused by mechanical interference, cannot be excluded.

In conclusion, this neurophysiological study shows that neurological deterioration after posterior laminectomy in these patients was due to grey matter damage and not to nerve root stretching. It is important to stress that the damage reversed spontaneously.

Different criteria in the assessment of visuospatial neglect

The classic manifestations of visuospatial neglect include (1) a certain minimal number of omissions in conventional neglect tests, and (2) a defective performance more pronounced at the side opposite the brain lesion.^{1,2} The procedure for assigning patients to the spatial neglect group typically includes a measure of the number of omissions in tests such as target cancellation, figure copying, and freehand drawing. A measure of the asymmetry of omissions is, however, not always included as a criterion for spatial neglect.^{3–5} Unless this is done, patients showing the typical pattern of visuospatial neglect may be mixed with patients showing no laterality in the defective performance.

The aim of this study was to compare the accuracy of the assignment of patients to the neglect group when using three different criteria for visuospatial neglect. A consecutive series of 60 right handed patients, mean (SD) age 60.25 (12.58); range 21–77 years with a single right hemispheric stroke were assessed one to eight weeks after stroke (mean (SD) 2.5 (1.53) weeks) using seven subtests from a shortened and slightly modified version of the behavioural inattention test. (The behavioural inattention test was

introduced by Wilson *et al* to offer a standardised test battery of unilateral visual neglect.³) Thirty four neurological healthy age matched right handed subjects served as controls.

The cut off level for defective numbers of omissions in each subtest and in the total number of subtests was represented by the first score below the normative range obtained from the control group. The asymmetry of defective performance was measured in the tests with scores at or below the cut off level. To avoid confusion of centrally and laterally located omissions, only the lateral parts of the test material were included in this measurement.⁶ The number of detected targets at the contralesional side was divided by the total number of detected targets⁷ and then represented by a percentage measure. The classification of the asymmetry of omissions was based on the range of laterality scores found in the control group (44–56%). It was classified as contralesional asymmetry if a laterality score below 44% was found in at least one of the tests and if no test was found with a score above 56%.

An assessment of hemianopia (by standard confrontational techniques) was included to analyse the influence of hemianopia on the asymmetric performance. Contralesional asymmetry as well as hemianopia were exclusively found in patients with neurological deficits remaining three weeks after stroke (in patients showing a major stroke, *n* = 41). No association between the presence of hemianopia (*n* = 15) and contralesional asymmetry (*n* = 18) was found in this group ($\chi^2 = 2.49$, *p* = 0.115).

In the present study, we compared three different criteria for assigning patients to the visuospatial neglect group, which are similar to criteria applied in recent studies of visual neglect^{4,5,7,8}: (1) a score at or below the individual cut off score in any of the seven subtests; (2) a total score at or below the aggregate cut off score for the seven subtests in the battery; (3) a score at or below the cut off level in at least one of the subtests and a contralesional asymmetry in the defective performance (as defined earlier). A significant difference was obtained between the proportions of patients defined as having visuospatial neglect when using the three criteria for neglect (*Q* = 19, *df* = 2, *p* < 0.001, Cochran *Q* test). The proportions were 45% (27/60), 23% (14/60), and 30% (18/60) respectively.

The criterion of individual cut off scores was the most generous method for classifying patients as having neglect. The use of this criterion resulted in nine patients (Nos 12, 15, 19–21, and 24–27) who were misidentified as having visuospatial neglect, although no contralesional asymmetry was found in the defective tests (table). These results show that visual inattention in a conventional test battery of neglect might be present with no contralesional asymmetry in the inattentive behaviour. The findings emphasise the importance of including not only visual inattention as a criterion for visual neglect, but also the asymmetry of the inattentive behaviour.

The aggregate cut off criterion was the most restrictive method for classifying patients as having neglect. Thus the table shows that five patients (Nos 16–18, 22, and 23) were classified as non-neglect patients, although the traditional neglect pattern with a defective number of omissions and a

Number of tests scoring below and at cut off, aggregate scores, and averaged laterality scores from patients showing defective scores in at least one subtest

*Aggregate scores within normal range. †Averaged percentage of detected targets at contralesional side in tests scoring at or below cut off. CA=Contralateral asymmetry; NA=no asymmetry (all tests within the range 44–56%). For No 12 and No 20 one subtest is missing. For No 19 two subtests are missing.

contralesional asymmetry was found in at least one of the tests. The use of this conservative cut off criterion represents an advantage in a situation where it is important to avoid a false inclusion of patients in the pathological group. In this case, a revised form of the aggregate scoring system including a criterion of asymmetric performance, might represent a favourable choice. This scoring system, however, might also be a disadvantage. It is well known that spatial neglect does not represent an all or none phenomenon. Thus excluding patients showing visual neglect in a small number of subtests in a test battery, presents a risk of excluding important information about subtypes of unilateral visual neglect.

The results indicate that the third criterion, which took account of the inattentive behaviour as well as the asymmetry of the defective performance, might offer a useful method for assigning patients to the neglect group. The application of this method made it possible to select not only patients with obvious indications of inattention but also patients with a mild inattention to the neglect group. At the same time a reasonable homogeneity of the laterality of the defective performance is maintained. Including the asymmetric performance in the criterion for neglect offers a methodological advantage, as it makes it possible to distinguish patients with an asymmetric performance from patients without an asymmetry in the defective performance.
