Extensive metabolic and neuropsychological abnormalities associated with discrete infarction of the genu of the internal capsule

F E Chukwudelunzu, J F Meschia, N R Graff-Radford, J A Lucas

Abstract

Objective—The clinical presentation of capsular genu infarct varies. Prominent faciolingual weakness and subcortical dementia are the rule, but symptoms depend on the precise location and extension of the lesion beyond the genu. The aim was to characterise the radiographic, electroencephalographic, and neuropsychometric abnormalities in a woman who had a history of recurrent transient memory loss.

Method—Case report.

Results—Magnetic resonance imaging showed an infarct in the genu of the left internal capsule. Positron emission tomography scan demonstrated decreased metabolic activity in the ipsilateral temporal, occipitotemporal, and contralateral cerebellar hemispheres. Electroencephalography showed intermittent rhythmic delta activity in the left frontotemporal region, and findings on neuropsychometric evaluation were consistent with cognitive impairment. Follow up evaluation 7 months after the stroke showed improvement in some areas of the cognitive domain, but residual neuropsychometric and neurophysiological abnormalities persisted.

Conclusion—This case illustrates that cerebral and cerebellar diaschisis may contribute to the symptomatic presentation and recovery from capsular genu infarct, although its precise role remains elusive.

Keywords: capsular genu infarct; amnesic syndrome; diaschisis

with dysarthria. Amnesic syndromes may result from lesions of the medial temporal lobe⁴ and diencephalon.⁵ Transient global amnesia⁶ can be easily distinguished from other amnesic syndromes on clinical grounds.

Recurrent transient amnesia limited to recent memory and culminating in ischaemic infarct of the genu of the internal capsule has not been reported. We report on a woman with infarction of the capsular genu who presented with episodic marked cognitive impairment associated with major verbal memory and language deficits. Results of detailed clinical, neuropsychological, and functional imaging studies suggest that cerebral and cerebellar diaschisis may contribute to the presentation and recovery from capsular genu infarction.

Case report

A 71 year old right handed woman with 12th grade education presented after acute onset of short term memory loss. Eleven years earlier, she had coronary artery bypass grafting for acute myocardial infarction. Over the previous 2.5 years, she had five discrete episodes of stereotypical short term memory loss, each lasting 15 to 20 minutes and completely resolving. Her fifth spell, 7 months before presentation, was evaluated by brain CT, transoesophageal echocardiography, and carotid duplex ultrasonography at another institution. No abnormality was found, and a diagnosis of transient global amnesia was made. Two days before presentation, while at church, her husband noted that she was unable to follow the service. Later that day, she could not remember her daughter's name or what day it was. The next day, she could not remember the events of the previous 24 hours and asked repetitive questions. Evaluation at the local emergency department a day later disclosed no other focal neurological symptoms. Results of a general physical examination were normal. Abnormal findings on neurological examination were disorientation to time and place and impaired 5 minute delayed recall. Results of laboratory studies, such as glucose, sodium, calcium, leucocyte count, haemoglobin, electrocardiography, and urinalysis, were normal. A diagnosis of transient global amnesia was made, and an outpatient neurological consultation was arranged.

Neurological evaluation 7 days after the onset of her symptoms disclosed no change in her symptoms. She was alert and cooperative but disoriented to place and time. She offered no spontaneous speech. Her response to questions was fluent but notable for delayed

Clinicoanatomical correlation of capsular genu infarct implicates the disruption of corticopontine and corticobulbar fibres as the cause of faciolingual and motor deficits often seen in these patients.¹ The cognitive impairment is attributed to interruption of the inferior and anterior thalamic peduncles² or diaschisis.³ In one of the largest case series, Tatemichi *et al*² reported that profound acute frontal lobe syndrome was manifested by fluctuating alertness, inattention, memory loss, apathy, abulia, and psychomotor retardation with minimal involvement of pyramidal and corticobulbar tracts. Some patients, however, had infarcts beyond the capsular genu. In a series by Bogousslavsky and Regli,¹ the most prominent findings were contralateral facial and lingual hemiparesis

Figure 1 Fluid attenuated inversion recovery magnetic resonance image showing hyperintense signals in the genu of the left internal capsule and periventricular and subcortical white matter.

response latency and word finding difficulties. Comprehension of conversational language was impaired, but she was able to follow a simple one step command. There were marked perseveration, apathy, and psychomotor retardation, with prominent frontal release signs (glabellar, palmomental, and snout). Motor examination showed normal gait with decreased right arm swing, mild drift, and decreased rapid alternating movements of the right hand. There was a mild upper motor neuron right facial weakness. Muscle stretch

reflexes were hyperactive, with an extensor plantar response on the right.

She was admitted to hospital, and brain MRI showed T2 weighted and fluid attenuated inversion recovery hyperintense signals in the genu of the left internal capsule and subcortical white matter (fig 1). Gradient echo MRI was negative for cerebral amyloid angiopathy. Electroencephalography showed left frontotemporal intermittent rhythmic delta activity. Transoesophageal echocardiography and magnetic resonance angiography of the intracranial and extracranial vessels yielded normal findings. Cerebrospinal fluid analysis showed 4 white cells and 6 red cells/ μ l, protein concentration of 41 mg/dl, and glucose concentration of 53 mg/dl (serum, 109 mg/dl). Results of CSF index, synthesis rate, oligoclonal bands, and fungal and viral cultures were negative.

A neuropsychological examination performed 2 weeks after the onset of her symptoms documented substantial cognitive compromise (table 1). Her performance on an expanded measure of mental status (dementia rating scale)⁷ was severely impaired for her age, with markedly deficient performances on subtests of attention (for example, digit span, visual scanning), initiation/perseveration (for example, word fluency), conceptualisation (for example, identifying oddities and similarities among verbal and visual stimuli), and memory (for example, orientation and immediate memory for words and figures). She was unable to retain information presented in the form of a word list from the Consortium to Establish a Registry for Alzheimer's Disease neuropsychological test battery⁸ or geometric designs from the Wechsler memory scale, revised (visual reproduction).⁹ Severe expressive and receptive language deficits were also evident. She had marked difficulty following auditory-verbal commands on the token test of the multilingual aphasia examination¹⁰ and comprehending short stories on the complex ideational material subtest of the Boston diagnostic aphasia examination.¹¹ Her ability to provide the names of line drawings of objects was also severely impaired (Boston naming test),¹² with errors characterised primarily by substitution of semantically similar words (for example, "arrow" for "dart," "dice" for "dominoes"). Her written mathematical skill and ability to recognise and pronounce written words were mildly impaired (wide range achievement test, 3rd edition).¹³ Her comprehension of the meaning of written sentences was more severely impaired (Peabody individual achievement test, revised; reading comprehension).¹⁴ By contrast, the patient showed relatively intact phrase repetition, spelling ability, and visuospatial constructional abilities. She endorsed moderate symptoms of depression on the geriatric depression scale.¹⁵

¹⁸F-2-fluoro-2-deoxy-D-glucose (FDG) positron emission tomography (PET) scan of the brain performed 7 weeks after symptom onset showed decreased metabolic activity in the left temporal, occipitotemporal, and right cerebellar hemispheres (fig 2). The PET scanner used an ADAC vertex coincidence camera with a

Figure 2 On ^{18}F FDG positron emission tomography images of the brain; decreased metabolic activity is apparent in the left temporal lobe (long arrows), occipitotemporal lobe (long arrows), and right cerebellar hemisphere (short arrow) 2 weeks after stroke.

matrix resolution of 128×128 . Five millicuries of FDG were administered. Treatment began with 325 mg aspirin, and speech and occupational therapies initiated in the hospital were continued for outpatient management.

Periodic follow up evaluation showed improvement in spontaneous speech, psychomotor retardation, and disorientation at 2 months after the stroke. A repeat neuropsychological evaluation 7 months after her stroke showed improvement in reading recognition, written mathematics skills, and memory for visual information to within normal limits for her age. Improvement was also evident on measures of language comprehension, naming, word fluency, and retention of verbal information; however, these performances remained in the impaired range for her age. No improvement was evident on measures of reading comprehension and verbal learning. Repetition and visuospatial abilities remained within normal limits for her age. Her responses to the geriatric depression scale mood inventory suggested only minimal symptoms of depression at the time of follow up. Table 1 summarises her cognitive assessments at 2 weeks and 7 months after the stroke. A repeat PET study of the brain (5 months later) showed incomplete resolution of the left cortical and right cerebellar hypometabolic defect.

Discussion

Remote focal metabolic effects in the brain, commonly referred to as diaschisis, are attributed to depressed synaptic activities at sites distant from, but neurally connected with, the damaged area.¹⁶ Several PET studies have demonstrated these remote metabolic effects in patients with large frontoparietal and thalamo-capsular strokes,^{17–19} but the precise relation to patients' symptoms and the prognostic value remain obscure. Some investigators have reported that cerebellar diaschisis does not resolve.^{20–22} Others have suggested that cerebral and cerebellar diaschisis is a transient phenomenon with potential for reversibility of the alterations and recovery of the deficits resulting from it.^{17–23–25} Bowler *et al*²⁶ investigated the contribution of diaschisis to clinical deficit in human cerebral infarction and concluded that

diaschisis does not independently add to clinical deficit after stroke. However, other investigators have found that crossed cerebellar diaschisis is greater with larger infarcts,^{21–27} but whether the degree of crossed cerebellar diaschisis correlates with clinical stroke severity remains controversial. Speculations that these remote effects underlie the neuropsychological deficits of subcortical origin²⁸ and contribute to diffuse symptoms of acute supratentorial strokes, such as confusion, agitation, and coma, have been difficult to prove.^{18–29–31}

Frontotemporal cortices have extensive connections with ipsilateral anterior thalamic nuclei and contralateral cerebellar hemisphere via the anterior and inferior thalamic peduncles. Corticothalamic and thalamocortical fibres form the thalamic peduncles. These fibres enter and exit the thalamus at its rostral and caudal poles and along the dorsal surfaces.^{32–33} The inferior thalamic peduncle carrying fibres connecting the ventromedial thalamus with the orbitofrontal, insular, and temporal cortices passes through the posterior capsule in the region of the genu.² Damage to this white matter tract may occur with infarction in the region of the inferior genu, causing severe amnesia from disruption of the basolateral limbic system.^{34–35} Interruption of the anterior or inferior thalamic peduncle, or both, in the region of the capsular genu has been proposed as the mechanism underlying the abrupt cognitive impairment seen in these patients.²

Functional brain imaging in our patient demonstrated hypometabolic activity in the temporal cortex ipsilateral to the capsular lesion, supporting the view that cognitive changes probably occurred by functional disruption, perhaps related to diaschisis. Periventricular and subcortical T2 signal abnormalities (leukoaraiosis) were present on brain MRI in our patient. Leukoaraiosis or white matter rarefaction has been reported to occur at a higher frequency in subjects with mild cognitive deficits and decreased mental processing.³⁶ According to one study, about one sixth of patients with stroke had pre-existing dementia previously undiagnosed, and leukoaraiosis and other factors were found to be independent

Table 2 Summary of case reports of isolated capsular genu infarcts

Authors, year	No. of patients	Symptoms at presentation	Recurrent symptoms	Location of lesion
Tatemichi <i>et al</i> , 1992 ²	1 of 6	Right hemiparesis, confusion	No	Left capsular genu
Bogousslavsky and Regli, 1990 ¹	5	Faciolingual weakness, dysarthria, dysphagia	No	Right (2) and left (2) capsular genu
Rousseaux <i>et al</i> , 1987 ³⁸	1	Left hemiparesis	No	Right capsular genu
Iwata, 1984 ³⁹	1	Right hemiparesis	No	Left capsular genu, corona radiata
Schnider <i>et al</i> , 1996 ⁴⁰	1	Confusion, amnesia	No	Right capsular genu, anterior thalamus
Yamanaka <i>et al</i> , 1996 ⁴¹	2	Abulia	No	Right (1) and left (1) capsular genu
Moreaud <i>et al</i> , 1996 ⁴²	1	Abulia, confusion, right facial weakness	No	Left capsular genu
Lai <i>et al</i> , 1990 ⁴³	1	Amnesia	No	Left capsular genu
Terao <i>et al</i> , 1991 ⁴⁴	1	Amnesia	No	Left capsular genu
Yamadori, 1990 ⁴⁵	1	Aphasia	No	Left capsular genu
Spertell and Ransom, 1979 ⁴⁶	1	Dysarthria, clumsy hand syndrome	No	Left capsular genu
Kooistra and Heilman, 1988 ³⁴	1	Memory loss	No	Left capsular genu
Markowitsch <i>et al</i> , 1990 ³⁵	1	Aphasia, right hemiparesis	No	Left capsular genu
Chukwudelunzu <i>et al</i> , present case	1	Amnesia	Yes (x5)	Left capsular genu

predictors of poststroke dementia.³⁷ Leuko-
araisosis and the possible coexistence of previ-
ously undiagnosed mild dementia may be con-
tributing factors in this case.

Review of the English literature uncovered
13 case reports of isolated capsular genu
infarcts.^{1 2 34 35 38-46} None of the patients had
stereotypic spells of marked cognitive impair-
ment before infarction as seen in our patient.
Among the 13 patients, amnesia was the major
presenting feature in four.^{40 43-45} A lesion was
seen in the left genu of the internal capsule in
three of the four patients. Table 2 summarises
the literature review of cases. Tatemichi *et al*²
reported detailed clinical and neuropsychologi-
cal long term follow up (10 weeks to 2 years)
findings in four of their six patients with capsu-
lar genu infarct. Resolution of acute dementia
syndrome occurred in only one patient 2 years
after stroke. Results of initial brain functional
imaging studies (¹³³Xe regional cerebral blood
flow and single photon emission computed
tomography (SPECT)) were abnormal in all
patients, but follow up studies were not
reported. Schnider *et al*⁴⁰ reported on a patient
with persistent abnormal neuropsychological
testing results 7 months after a capsular genu
stroke. In a case report by Moreaud *et al*,⁴² PET
demonstrated hypometabolism in the left fron-
totemporoparietal, left caudate, left thalamus,
and right cerebellar cortices 2 months after a
left capsular genu infarct. Follow up SPECT
studies in two patients reported by Yamanaka *et al*⁴¹
showed persistent abnormality in one and
resolution in the other 4 and 6 months after
stroke, respectively. Kooistra and Heilman³⁴
and Markowitsch *et al*³⁵ reported similar cases
with persistent cognitive abnormalities on
neuropsychological testing 2 years and 9
months after capsular genu infarction. Our
case report is similar to previously reported
cases, but in addition to long term follow up
with detailed clinical and neuropsychological
testing, we showed that clinical and neuro-
psychological findings were correlated with
those of PET studies.

In our patient, the relevant lesion lies in the
distribution of anterior perforators arising from
the apex of the internal carotid artery^{47 48} or the
anterior cerebral artery.^{48 49} The essential fea-
tures of this capsular genu "cognitive syn-
drome" resemble the clinical profile found in
unilateral polar thalamic infarction^{50 51} or the
dementia syndrome of bilateral paramedian

thalamic infarction.⁵² Among 100 patients with
lacunar infarcts in the territory of deep
perforators of the carotid system identified by
CT, Ghika *et al*⁵³ found neuropsychological
deficits in up to 34%. Thus, capsular genu in-
farct causing acute cognitive impairment may
not be uncommon and may be underreported.

A chance association between the infarct and
our patient's presentation cannot be excluded
with certainty. Her underlying cardiac condi-
tion may have contributed to her memory loss.
It is also possible that our patient had transient
epileptic amnesia⁵⁴ and that the infarct was
coincidental. A trial of anticonvulsant drugs
and ambulatory electroencephalography were
not performed.

Although our patient's disorientation, apa-
thy, psychomotor retardation, and mood and
some of her cognitive functions improved 7
months after the stroke, neuropsychological
evaluation and PET studies showed persistent
abnormalities beyond the area of the structural
lesion. The infarct was limited to the white
matter without involvement of the adjacent
grey matter structures. No mass effect to adja-
cent structures was demonstrated on brain
MRI. The implications are that the cerebral
and cerebellar diaschisis in this patient may
have contributed to her inadequate clinical
recovery. This case supports the phenomenon
of cerebral diaschisis as a possible contributing
mechanism to poor recovery from a small but
strategically placed ischaemic infarct.
