Conflict and integration of spatial attention between disconnected hemispheres

The article by Dr Ishiai and colleagues contains a critical piece of anatomical data (that is, the “sparing of the rostrum and the inferior half of the genu” (fig 1)) which has been ignored by the respected authors as to its probable role in underpinning the results they reported. This may have occurred because of their conventional theoretical perspective on motor control in the human, in the light of which such matters might be afforded. However, the doctrine of contralaterality of movement control (CMC) in humans has given. This may have occurred because of the conventional theoretical perspective on motor control in the human, in the light of which such matters might be afforded. However, the doctrine of contralaterality of movement control (CMC) in humans has not been recently revised to account for observations such as theirs in the sensory realm, as well as others in the motor realm that underpin the classical laterality indexed trilogy of callosal hemiplegia/ipsilateral apraxia (with and without speech deficit); ipsilateral (non-dominant) weakness in lesions affecting the major hemisphere; and non-dominant weakness in lesions affecting the caudal sulcus. The one-way callosal traffic theory (underpinning lateralities of executive functions) states that all voluntary actions involving the non-dominant hand entail a sequential activation (that is, major followed by minor hemisphere, mediated through the callosum) of a devoted neuronal aggregate distributed between two hemispheres. The commands for the effectors on the dominant side reach them directly whereas they arise. Those for the non-dominant effectors traverse the callosum. Evidence favouring this scheme is overwhelming, as detailed elsewhere. Thus the improvement of performance seen upon the voluntary movement of the non-dominant side reflected the activating effect on both hemispheres when the left hand moved voluntarily, temporarily “lightening up” the rostral right hemisphere through the remaining functioning callosal connections depicted on MRI. The new scheme, therefore, bypasses the controversies mentioned by the authors. It is to be noted that this scheme relates to all movements, whether cranial (such as eye movements) or appendicular. Anyone in doubt of the veracity of this claim can find solace when they hear a double click upon snapping their fingers simultaneously, instead of one click mandated by CMC doctrine, with the second click arising from the neural (as opposed to ostensible) non-dominant hand (Derakhshan I, unpublished data). The callosal delay imposed on the non-dominant hand has been known for 160 years, under the name Melody Lead of the right hand of piano players, and is thought to represent artistic expression. Its range, however, (10–40 ms) makes that interpretation highly unlikely. Callosal delay when turning the eyes to the non-dominant side has long been documented. However, for the reasons alluded to earlier, more modern workers have ignored it, some calling it “idiosyncratic.” An interpretation inconsistent with the consistency it shows itself when sufficient data are given.

Cerebral vasospasm

Edited by R W Seiler and HJ Steiger (Pp 269, €108.00) Published by Springer-Verlag, Wien, 2001. ISBN 3-211-83650-0

This book contains the proceedings of the Seventh International Conference on Cerebral Vasospasm held in Interlaken Switzerland in June 2000. It is one of a series of books of proceedings produced by Springer where the scientific work has also been recently published as a supplement in Acta Neurochirurgica.

The book begins with a brief overview of cerebral vasospasm as a clinical problem. It then presents the various papers from the meeting laid out in two parts. Part I refers to basic science and experimental vasospasm and Part II the diagnosis and therapy of clinical vasospasm. Part I has sections on molecular biology of vasospasm, endothelial and nitric oxide gene therapy, and experimental vasospasm, while Part II has the sections on diagnosis, microdialysis and metabolic monitoring with tis- one day, preoperative, and postoperative cerebral vasospasm, cerebral vasospasm, and experimental vasospasm, while Part II has the sections on diagnosis, microdialysis and metabolic monitoring with clot-lysis to prevent vasospasm, endovascular treatment, neuroprotection, and haemodynamic therapy.

Like all proceedings it is in essence a collection of papers that represent the latest research and thoughts on the subject. As a
result it is a little disjointed but this has been addressed by grouping the papers under the headings above. It is neither a comprehensive review of vasospasm nor is it meant to be. It is nevertheless a very interesting and informative book and does give a very useful insight into the direction in which research is heading. It is therefore very helpful for researchers in the field and would make a useful addition to a neurosurgical or neuroscience library.

Kevin O’Neill

Contemporary approaches to the study of hysteria, clinical and theoretical perspectives

This book ranges more widely than its title implies, including sections on somatisation disorder, factitious disorder, and malingering. Indeed, much the same territory as covered by somatisation, also edited by Christopher Bass and published in 1992. A comparison of the two multi-authored compilations provides a fair indication of progress over the past decade.

Perhaps the most positive development is that the Slaterian heresy (that to diagnose hysterical conversion is to miss an organic disorder) seems finally to have been laid to rest. Hysterical conversion, conversion, dissociation—whatever you care to call it—exists, the problem is: what is it? The paradox is laid bare in a chapter by Wessely: Conversion (or somatisation) is a psychiatric disorder that is diagnosed by neurologists on essentially negative grounds. The so-called positive features—for example, primary gain—can rarely be convincingly elicited, which is hardly surprising: a conscious awareness of primary gain would vitiate the whole conversion process. The lack of a firm theoretical basis worries most authors, but thoughtful sections on functional neuro-imaging (in spite of there being little data) and the role of hypnosis point the way forward. Clinical interests are well served: in particular chapters on prognosis and on neurological assessment. The editors have strained to achieve a balance between the old and the new: the price to be paid for this is three chapters on psychodynamic theory where one would more than suffice. This apart, the book provides an excellent tour d’horizon of hysteria and allied disorders as they enter the 21st century.

Mind of matter, a neurologist’s view of brain behaviour relationships

The subtitle of Heilman’s enjoyable book, “a neurologist’s view of brain behaviour relationships”, suggests a philosophical, reflective work. It is, in fact, an informal but sober review of the main areas of behavioural neurology to which Heilman has contributed during his long and productive career.

It has several strengths: personal cases illustrate the topics, personal anecdotes enliven them, and Heilman’s logical mind guides the reader judiciously through the twists and turns of neuropsychology. I particularly enjoyed his chapters on attention, self awareness, and praxis, all subjects on which he has worked.

Trained by Norman Geschwind, well versed in the old European tradition of cortical localisation, Heilman’s emphasis is strongly clinical. Experimental work in animals and functional imaging are largely off stage. In keeping with its informal approach the book is only lightly referenced: a pity, for some readers.

The book introduces a number of challenging generalisations. Heilman takes up Denny Brown’s suggestion that the parietal lobes are the “seat of knowing” and in this work inject the necessary measure of “avoidance”, enabling us to judge when approach is wise. He sketches a series of contrasts between the hemispheres: he links the left hemisphere with propositional aspects of language, “focal” perceptual processes, object recognition, restricted (right-sided) spatial awareness, positive emotions, and knowledge of “how” to get things done; he associates the right hemisphere with emotional aspects of language, “global” perceptual processes, face recognition, and emotional awareness. Heilman adds that to this can be added the condition to current understanding of pathogenesis and pharmacology. It covers the medical aspects of vasospasm as well as the surgical aspects and touches on future research directions by looking at molecular biology and the genetics of vasospasm.

It has brought together a vast amount of information from a number of sources and presented it in a very well analysed and systematic fashion. I would agree with Neil Kassell’s foreword that this is indeed a magnum opus and would play and important role in finding a remedy for vasospasm. I would add that it is a must read for any neuroscientist currently undertaking research into the subject and indeed would be a valuable background text for any neurosurgeon in training.

Cerebral vasospasm

As many readers will appreciate, cerebral vasospasm is well recognised as a major cause of morbidity and mortality of patients following subarachnoid haemorrhage. Despite the huge amount of work done both in the laboratory and clinical setting the pathogenesis and pathophysiology of this disorder is only partially understood. As a result effective treatment options remain elusive. Macdonald and Weir are pre-eminent in this field, having devoted much of their lifetime research efforts to it. They therefore compile this book from the position of much authority.

Having researched into vasospasm myself, I realised that to make progress in understanding the pathogenesis of vasospasm required a multifaceted approach. Most of the work that had been done and was being done was very focused and therefore the knowledge base fragmented. In essence we were not seeing the whole picture. This book addresses that problem and is the most comprehensive and detailed work on the subject.

It covers information on the history of the condition to current understanding of pathogenesis and pharmacology. It covers the medical aspects of vasospasm as well as the surgical aspects and touches on future research directions by looking at molecular biology and the genetics of vasospasm.

It has brought together a vast amount of information from a number of sources and presented it in a very well analysed and systematic fashion. I would agree with Neil Kassell’s foreword that this is indeed a magnum opus and would play and important role in finding a remedy for vasospasm. I would add that it is a must read for any neuroscientist currently undertaking research into the subject and indeed would be a valuable background text for any neurosurgeon in training.
