ABSTRACT

Objective The objective of this study was to evaluate peer support and reminiscence therapy, separately and together, in comparison with usual care for people with dementia and their family carers.

Design Factorial pragmatic randomised trial, analysed by treatment allocated, was used for this study.

Setting The trial ran in Community settings in England.

Participants People with dementia and their family carers were the participants.

Interventions Treatment as usual (TAU) plus one of the following: one-to-one peer support to family carers from experienced carers (Carer Supporter Programme; CSP), group reminiscence therapy (Remembering Yesterday, Caring Today; RYCT) for people with dementia and carers, both or neither.

Main outcome measures Primary outcomes included health-related quality of life (SF-12) for carers and quality of life (QoL-AD) for people with dementia; secondary outcomes included quality of relationship for carers and people with dementia; both were collected by blinded assessors at baseline, 5 and 12 months (primary end point).

Results Of 291 pairs recruited, we randomised 145 (50%) to CSP (71% uptake) and 194 (67%) to RYCT (61% uptake). CSP and RYCT, separately or together, were not effective in improving primary outcomes or most secondary outcomes. For CSP versus ‘no CSP’, adjusted difference in means was 0.52 points on the SF-12 (95% CI −1.28 to 2.32) and −0.08 points on the QoL-AD (95% CI −1.70 to 1.56). For RYCT versus ‘no RYCT’, the difference was 0.10 points on the SF-12 (95% CI −1.72 to 1.93) and 0.51 points on the QoL-AD (95% CI −1.17 to 2.08). However, carers reported better relationships with the people with dementia (difference 1.11, 95% CI 0.00 to 2.21, p=0.05).

Comparison of combined intervention with TAU, and of intervention received, suggested differential impacts for carers and persons with dementia.

Conclusions There is no evidence from the trial that either peer support or reminiscence is effective in improving the quality of life.

Trial registration number ISRCTN37956201; Results.

INTRODUCTION

The lack of progress in new drug treatments for people with dementia has contrasted with recent advances in psychological interventions. In the UK, there have been large randomised controlled trials of cognitive–behavioural therapy (CBT) and befriending as interventions for carers, cognitive stimulation therapy (CST) for people with dementia and reminiscence therapy for carers and people with dementia. The evaluations of CBT for carers and CST for people with dementia have demonstrated the effectiveness of these interventions in reducing distress and maintaining cognition, respectively. In contrast, there is no evidence that befriending or joint reminiscence reduces distress, even though they are recommended in clinical guidelines and remain popular in practice. Peer support may be more effective than befriending in addressing carers’ needs and may also enhance reminiscence therapy. Hence, this trial aimed to evaluate two psychological interventions, namely one-to-one peer support for carers (Carer Supporter Programme; CSP) and group reminiscence therapy for people with dementia and their carers (Remembering Yesterday Caring Today; RYCT), together and separately.

METHODS

The trial protocol describes the research question, sample size calculation, recruitment, consent, randomisation, interventions, outcome measures, ethical considerations and research governance.

Design We used a multisite, 2×2 factorial, pragmatic randomised trial. The factorial design in effect is ‘two trials in one’, enabling us to evaluate both treatments. We consented participating carers, collected baseline data and randomised them individually between CSP and treatment as usual (TAU), and then randomised them between RYCT groups and TAU. This created four arms—CSP, RYCT, CSP and RYCT, and TAU alone. To yield enough participants to run viable RYCT groups, randomisations between TAU, CSP, RYCT and CSP–RYCT were in the proportions of 1:2:1:2. At the first randomisation, we stratified by kinship (whether carers were spouses or offspring) and centre. At the second randomisation, we also stratified by the first allocation to keep the four arms in balance. We collected follow-up data 5 and 12 months (main end point) after the first randomisation.

In accordance with MRC guidance on developing and evaluating complex interventions, we piloted in two London boroughs before the full trial: the first borough reviewed the
appropriateness and acceptability of procedures, and the second
borough checked logistics and timing of the interventions. We
described the resulting decisions on pooling pilot and main trial
data elsewhere. As changes between pilot and full trial were
minimal, we carried pilot data forward to the full trial.

Ethics approval
The Outer North East London Research Ethics Committee gave
written ethics approval (09/H0701/54). We obtained Research
and Development approval from local trusts. All participants
gave written informed consent.

Setting
The trial ran in community settings in London, Berkshire,
Norfolk and Northamptons.

Eligibility criteria
Participants were adult (18 years and over) family carers and
their relative with dementia (as defined by DSM-IV criteria)
living at home in the community. We excluded carers if they or
their protégés had learning disability, non-progressive brain
injury or diagnosed terminal illness, or they were already taking
part in another psychosocial intervention study.

Sample size
We based sample size on the BECCA2 and REMCARE9 trials.
These predicted effect sizes, namely average effect per partici-
pant divided by population SD, of 0.42 for CSP and 0.35 for
RYCT. Hence, a completed sample of 240 pairs would yield
power of more than 90% to detect these effects using a signifi-
cance level of 5%. This would also yield power of more than
80% to detect interaction between CSP and RYCT equivalent to
an effect size of 0.4. Assuming 80% retention, we aimed to
recruit 300 pairs of carers and people with dementia.

Interventions
For CSP, volunteer carer supporters (CSs) were recruited locally
by CS Coordinators and attended a mandatory ‘Being a Carer
Supporter’ orientation and awareness course before being
matched with a family carer participant. The target ‘dose’ was
12 weekly meetings of 1 hour, followed by fortnightly meetings
for the next 5 months, 22 hours in total. Meetings took place in
the carer’s own home, or a public venue like a café, or over the
telephone, and could include or exclude the person with
dementia according to the preference of the family carer. We
asked CSs to listen, encourage and give moral support. Though
they could also signpost to resources and services, we instructed
them not to offer tangible support, respite or direct advice.

The RYCT intervention followed Schweitzer and Bruce’s9
programme. Twelve weekly sessions took place in community
venues, each lasting 2 hours, covered themes across the lifespan,
using multisensory triggers and activities, such as group discus-
sions, small group activity, handling objects, acting or improvisa-
tion, and singing. During four sessions, the family carers met
separately from the main group for ~45 min with the aim of
developing listening and communication skills, and considering
how the activities and strategies in the sessions could continue
in the home. After the weekly sessions, monthly sessions contin-
ued for 7 months, giving a possible 19 sessions over 10 months.
To address the potential time burden of the combined interven-
tion, we invited CSs to meet their matched carers at the RYCT
sessions.

We had a planned protocol for assessing intervention delivery
and receipt.10 Delivery of CSP was monitored by local CS
Coordinators through monthly completion of checklists, and
RYCT adherence was recorded for each session by a participat-
 ing research assistant. We ensured that all participants continued
to receive the TAU available in their area and gave them lists of
useful local resources.

Measures
We collected demographic information for carer and person
with dementia, including age, gender, education, kinship and
living circumstances. We characterised carers’ social networks
according to the Practitioner Assessment of Network Typology
(PANT).11 We measured the cognitive status of the person with
dementia by the mini-mental state examination (MMSE)12 and
the interviewer rated the clinical dementia rating (CDR).13

Primary outcomes
The primary outcome was family carers’ mental health-related
quality of life, measured by the mental component score of the
UK Short Form-12 Health Survey (UK SF-12).14 15 The SF-12
covers physical functioning, social functioning, role functioning
(physical and mental), vitality, bodily pain, mental health and
general health, and it generates mental and physical component
scores (MCS-12 and PCS-12, respectively).

The primary outcome for the person with dementia was
quality of life measured by the 13-item Quality of Life—
Alzheimer’s Disease Scale (QoL-AD).16 Responses for both ver-
sions—completed by self or proxy—range from poor (1),
through fair and good to excellent (4), yielding totals in the
range between 13 and 32.

Secondary outcomes for family carers
Health-related quality of life using the EQ-5D17 comprising five
items generating a single utility score and a visual analogue scale
(VAS) to rate one’s general health, Hospital Anxiety and
Depression Scale (HADS).18 Emotional Loneliness Scale,19
Caregiver Distress Scale of the Neuropsychiatric Inventory
(NPI-D),20 positive scale from the Positive and Negative Affect
Schedule (PANAS).21 Positive Aspects of Caring (PAC) using
the four-item positive aspects subscale from the Carers of Older
People in Europe Index (COPE index),22 three-item Personal
Growth Index (PGI),23 and Quality of Caregiver–Patient
Relationship (QCPR).24

Secondary outcomes for the person with dementia
These included the EQ-5D, HADS and QCPR, as for family
carers. Family carers rated the functional capacity of the person
with dementia in activities of daily living using the Alzheimer’s
Disease Cooperative Study—Activities of Daily Living Inventory
(ADCS-ADL).25 We also assessed their quality of life by the
DEMQOL26 completed by self and carer.

Blinding
The nature of the interventions prevented us from blinding par-
ticipants and providers to their allocated group. However, we
blinded research interviewers by provided interventions inde-
pendently of their assessments. After interview, researchers
recorded their perceptions of participants’ allocation. This
showed no evidence of bias due to non-blinded researchers.

Data management and statistical analysis
We entered data into Infermed’s MACRO Electronic Data
Capture system for clinical trials. We audited a randomly
selected 10% sample of data for each site at each time point, to
ensure that the MACRO database was consistent with paper

questionnaires. We corrected all errors and inconsistencies, transferred the resulting data to the Statistical Package for the Social Sciences (SPSS V20) and undertook further checking, notably for out-of-range values.

Where individual items were missing within scales or subscales, we imputed them before calculating scale or subscale scores. We prorated measures with at most 20% of items missing; for example, if one of five items was missing, we imputed this by the mean of the other four items. We also made multiple imputations within time points, unless all measures were missing at that point. Multiple imputations were calculated using a linear regression model taking into account demographic variables (carer gender, centre, carer age, living status for carer outcomes; carer gender, person with dementia gender, centre, carer age, person with dementia age, living status, baseline MMSE and CDR for person with dementia outcomes), treatment group and other scores provided at a given time point. Using a multiple imputation method allowed an assessment of the sensitivity of the data to the imputations used.

The trial statistician (ZH) carried out all statistical analyses, mostly following a predefined analysis plan by ‘treatment allocated’. We estimated the two main effects by comparing CSP (alone or in combination with RYCT) with no CSP (TAU or RYCT alone); and RYCT (alone or in combination with CSP) with no RYCT (TAU or CSP alone), including interaction between CSP and RYCT in each analysis. We used multilevel analysis of covariance with follow-up data as dependent variable and baseline score as covariate. We treated group allocation, gender and kinship as fixed effects, and centre and time as random effects. When a main effect or interaction term was significant, we repeated the analysis by comparing the combined intervention with TAU. Finally, to explore whether ‘treatment received’ could explain these pragmatic analyses by

Figure 1  Flow of participants through study.
‘treatment allocated’, we undertook a form of dose-response analysis by adding the numbers of CSP contacts, RYCT sessions attended and RYCT sessions attended by a CS to the model.

Patient involvement
Psychosocial interventions are a high priority for people with dementia and family carers. Former family carers were involved in the development and delivery of the CS intervention. Results have been shared with study participants through a lay final report and a stakeholder dissemination event.

RESULTS
Participant flow
Figure 1 shows the flow of participants through the trial. The research team received 640 expressions of interest from carers and screened all but one for eligibility. Of these, they excluded 347, notably 180 because carers declined, 66 because researchers could not contact carers and 33 because carer had too little time. Of the 292 family carers who consented to the research, 1 and screened all but one for eligibility. Of these, they excluded 347, notably 180 because carers declined, 66 because researchers could not contact carers and 33 because carer had too little time. Of the 292 family carers who consented to the research, 1 withdrew before randomisation, but the rest completed the baseline assessment and were randomised between January 2010 and March 2012. However, two provided no data at any time point. As we collected no information about potential participants before they consented, we cannot assess whether those who participated differed from those who declined or those whom we excluded from the trial.

Stress, time constraints or the poor health of carer or relative with dementia caused 36 carers to withdraw before the first follow-up after 5 months; 2 of these reappeared for the final follow-up after 12 months. Thus, 253 carers completed the first follow-up. As 241 completed the final follow-up, we retained 83% of the participants through 12 months. Loss to follow-up was greater, but not significantly greater, in the TAU group (23%) than in those allocated to 1 of the 3 interventions (15%).

Baseline characteristics
Tables 1 and 2 show baseline demographic and clinical characteristics of family carers and people with dementia, respectively. Most family carers were white British (89%), women (67%), spouses (64%) and had had only school education (62%). Their mean age was 67 years, of which they had spent an average of more than 4 years in caring, more than 2 of these since diagnosis. Most people with dementia were white British (88%), women (53%), residing with their carer (68%), and had had only school education (75%). Their mean age was 80 years. Alzheimer’s disease was the most common diagnosis, followed by vascular dementia, although a significant proportion had no specific diagnosis recorded.

Though allocated groups were broadly similar, there were non-significant differences that could have distorted findings if we had not used analysis of covariance, notably people with dementia in the TAU group were less impaired on the MMSE.

than other groups. To strengthen our analysis, we added MMSE as a covariate for people with dementia. Though ethnicity varied between groups, there was a greater variation between centres, with the proportion of white British carers ranging from 72% to 100%, reflecting the local populations from which we recruited participants.

Effectiveness

Tables 3 and 4 show the results of analyses after 12 months by treatment allocated for family carers and people with dementia, respectively.

For family carers, there was no significant main effect or interaction for the main outcome (health-related quality of life, SF12). For CSP versus ‘no CSP’, the difference in means was 0.52 points on the SF-12 (95% CI –1.28 to 2.32), and for RYCT versus ‘no RYCT’, the difference in means was 0.10 points on the SF-12 (95% CI –1.72 to 1.93). Neither was there any main effect or interaction for any secondary outcome, except for the quality of relationship, where imputed data showed significant benefit for CSP over ‘no CSP’ in the absence of criticism and conflict. The adjusted difference in means was 1.11 (95% CI 0.00 to 2.21, p = 0.05). Comparison of the combined intervention with TAU (table 5) showed that by 12 months, CSP–RYCT had also improved carers’ perceived quality of the caring relationship. The difference in means was 3.13 (95% CI 0.42 to 5.83, p = 0.03).

The results for people with dementia are more complex. There was no significant main effect for the main outcome (QoL-AD) at 12 months (CSP vs ‘no CSP’ difference in means –0.08 points, 95% CI –1.70 to 1.56; RYCT vs ‘no RYCT’ difference in means 0.51 points, 95% CI –1.17 to 2.08). However, the interaction between CSP and RYCT was significant (p = 0.02), suggesting that the effectiveness of the combination might be different. The comparison of the combined intervention with TAU showed no significant effect on QoL-AD. Instead, CSP–RYCT adversely affected proxy-reported DEMQOL relative to TAU (difference in means –4.31, 95% CI –8.19 to –0.44, p = 0.03 at the first follow-up). Similarly, CSP adversely affected proxy-reported DEMQOL (difference in means –3.18, 95% CI –6.15 to –0.22, p = 0.04).

Completers versus non-completers

We used Fisher’s exact tests and Mann-Whitney U tests to compare baseline characteristics of those 241 pairs who completed the final follow-up with those 50 who withdrew before then. However, we found no significant difference in any demographic characteristics (carers’ gender (p = 0.74), age (p = 0.12), ethnicity (p = 0.67), marital status (p = 0.62), level of education (p = 0.76)); dementia characteristics [type of dementia (p = 0.53), neuropsychiatric symptoms (NPI, p = 0.24), time since diagnosis (p = 0.56)]; kin relations (spouses/partners vs non-spouses p = 0.37); cohabitation (p = 0.12); or psychological

**Interpretations:**
- The primary analysis at 12 months showed no significant differences between the groups.
- The combined intervention (CSP + RYCT) showed a trend towards better outcomes compared to TAU.

### DISCUSSION

Through this trial, we sought to answer the question ‘do peer support or reminiscence therapy have an impact on the quality of life of family carers of people with dementia?’ There was no indication from the trial to suggest that either peer support or reminiscence therapy had a significant effect on the measured outcomes.

Primary analyses 12 months after randomisation showed no benefit to family carers of peer support or reminiscence therapy on their many outcome measures; the only exception is that carers who attended at least one RYCT session reported higher, but not significantly higher, quality of life. This may reflect the known tendency of people with dementia to rate their quality of life more highly than do their relatives. However, the carer versus person with dementia rating discrepancy was not evident in any of the other comparisons.

Our lack of findings are in keeping with many other randomised controlled trials of psychological interventions for family carers of people with dementia where no measurable effect has been found for popular interventions.

### Strengths and limitations

We drew participants from a wide range of community settings and included those already embedded in services and new users.
of those services. We adopted broad inclusion criteria reflecting the wide range of UK settings. Both interventions benefited from well-developed manuals and training for all providers. The follow-up interviewers were blind to participants from well-developed manuals and training for all providers. The price of one port or allowing carers to attend reminiscence sessions without overlapping interventions by sequential randomisation procedures. However, we adapted the original trial protocol for each intervention to create a protocol that could deliver both. For example, the eligibility criteria for reminiscence therapy usually exclude people with dementia with agitation or severe cognitive or physical impairment. Nevertheless, we enrolled them as eligible for home-based peer support. Where possible, we adapted interventions accordingly, for example by hiring specialist transport or allowing carers to attend reminiscence sessions without their relatives. As we could not accommodate all such needs within the interventions, however, recruitment fell, but not below our targets.

Factorial designs are less easy to interpret. They generate four groups, of which three receive interventions, but only one gets TAU. However, the main analyses reduce these four groups to two: to evaluate peer support, analysis compares those allocated to support with or without reminiscence therapy with those not so allocated, and to evaluate reminiscence therapy, analysis compares those allocated to reminiscence with or without peer support with those not so allocated. These analyses assume that peer support and reminiscence do not interact in the sense that one potentiates or weakens the other. However, three of many interactions we tested were significant. Hence, we interpret the corresponding non-significant main effects with caution. Though we addressed this issue by comparing the combined intervention with TAU, this comparison does not have as much power.

**Differences between this and other studies**

*Intervention:* In this trial, we refined both interventions better to meet the needs of family carers, using past carers of people with dementia rather than lay befrienders increased rapport

*Combines intervention.
†Coefficients represent the mean change in outcome with change in number of sessions attended when all other variables in the model are constant; negative coefficients show that outcomes deteriorate as attendance increases.
ADCS-ADL, Alzheimer’s Disease Cooperative Study—Activities of Daily Living; COPE, Carers of Older People in Europe; NPI-D, Neuropsychiatric Inventory Caregiver Distress Scale; CS, carer supporter; DEMOQL, quality of life for people with dementia; EQ-SD, EuroQol 5 dimensions; HADS, Hospital Anxiety and Depression Scale; MCS, mental component score; PAC, Positive Aspects of Caring; PANAS, Positive and Negative Affect Schedule; PCS, physical component score; QCPR, Quality of Caregiver–Patient Relationship; QoL-AD, Quality of Life in Alzheimer’s Disease Scale; SF, short form.

Differences between this and other studies

*Intervention:* In this trial, we refined both interventions better to meet the needs of family carers, using past carers of people with dementia rather than lay befrienders increased rapport

between participating carers and their supporters and reminiscence therapy put more emphasis on carer support and education than in the REMCARE trial.

Design: We adopted a factorial design capable of evaluating both interventions simultaneously, and testing whether they potentiate each other.

Population: We recruited more non-white carers and people with dementia than previous dementia care trials had performed in the UK. There were significant differences between carers of different ethnic backgrounds, with South Asians reporting most distress and African Caribbean carers least.

Uptake: This varied between groups. Uptake of carer interventions in trials is often low, which threatens trials analysed by treatment allocated. In contrast, the success of the START trial was due at least in part to very good uptake by carers. 3

Findings: The paucity of benefit to carers is consistent with previous trials of befriending4 and reminiscence.5 However, we did not see the REMCARE finding of increased anxiety in carers receiving reminiscence therapy.4 Instead, our qualitative evidence6–8 aligns with other evidence that peer support and reminiscence therapy are valued and enjoyable activities.9

Previous carer intervention research has received criticism for not studying impact on people with dementia.

Unanswered questions and future research
Peer support and reminiscence therapy are attractive in principle, but neither has yet generated evidence of effectiveness. By adopting a factorial design, we sought to test whether they potentiate each other; however, this was also ineffective. Interventions targeting people with dementia and their carers have gained in popularity. The findings of this research raise questions about how best to balance the needs of the family carer and his or her relative with dementia. It also reinforces the need to study the impact of interventions on both parties.

CONCLUSIONS
Despite enhancing the carer support component of peer support and reminiscence, this trial confirms previous findings that neither intervention is effective. The quantitative results are at odds with findings from qualitative studies of the same interventions. Research in this field should now seek to identify which carers and people with dementia can benefit from which psychosocial interventions.

Acknowledgements
The CSP–RYCT trial (ISRCTN37956201) was part of the ‘Support at Home—Interventions to Enhance Life in Dementia (SHIELD)’ research programme. The grant holders were Professors Orrell (UCL—Chief Investigator), Challis (Manchester), Knapp (LSI and KCL), Moniz-Cook (Hull), Russell (Swansea), Woods (Bangor) and Dr Charlesworth (UCL). The authors thank all of the family carers, people with dementia, and CS and RYCT volunteers; members of the programme steering committee James Lindsey (Chair), Vincent Kirchner, Jan Oyebode, Rachel Thompson, Jayne Dunn, Graham Stokes, David Prothero (family carers, people with dementia, and CS and RYCT volunteers; members of the programme steering committee James Lindsey (Chair), Vincent Kirchner, Jan Oyebode, Rachel Thompson, Jayne Dunn, Graham Stokes, David Prothero), and data monitoring committee Jill Manthorpe (Chair) and Jennifer Helliwell. CSP–RYCT site principal investigators were Georgina Charlesworth (North East London NHS Foundation Trust), Gwen Bonner (Berkshire Healthcare NHS Foundation Trust), Margaret Fox and Fiona Poland (University of East Anglia for the Norfolk & Waveney Mental Health NHS Foundation Trust site) and Sue Roy (Northamptonshire Healthcare NHS Foundation Trust). The voluntary organisations who supported carers included Age Concern Havering (now Tapestry), Age UK Norfolk, Carers of Barking and Dagenham, Redbridge Respite Care Association and Waltham Forest Carers Association. The web-based randomisation system and MACRO databases were developed in collaboration with North Wales Organisation for Randomised Trials in Health (NWORTH).

Collaborators
Fiona Poland is the PPI lead for this study.

Contributors
GC, BW, IR and MO participated in the design and conduct of all stages of the research. JW was programme coordinator, ZH was trial statistician, MK was health economics adviser and IR was methodological adviser. JW, NK and KB were trial managers at different states of the research. RYCT Consultant and trainer was Pam Schweitzer. JW oversaw provision of the RYCT intervention throughout the study, with groups led locally by Yvette Kusel, Janet Jones, Caroline O’Haire, Jackie Illies, Barbara Parkinson, Dianne Collins, Gurjinder Loyal and Rebecca Whitaker. Shaheen Ahmed gathered data on CSP intervention from local CS Coordinators Anne Losham, Mary Woodford, Maggie Playle, Liz Sturgess, Doreen Harrison and Lumbini Vithana. Researchers Nadia Crellin, Elizabeth Harte, Alexandra Feast, Nina Melunsky, Emma Patten, Teresa Sullivan, James Sinclair and Deepak Sankhla collected and entered data from participating carers and people with dementia. GC, KB, NC, ZH, JH, MK, IR, JW, BW and MO participated in all stages of manuscript preparation and approved the final version. GC is the guarantor.

Funding
The SHIELD research programme was sponsored by the North East London NHS Foundation Trust and funded by the National Institute for Health Research (NIHR) programme grant number RP-PG-0606-1083. Additional sources of funding for each site: North East London; Central and East London CLRN (CEL1042); Northampton; Leicester, Northamptonshire, and Rutland CLRN and Thames Valley DeNDRoN: Norwich; Norfolk & Suffolk Health Innovation and Education Cluster (HIEC) and East Anglia DeNDRoN: Berkshire; and Thames Valley CLRN and Thames Valley DeNDRoN. The views expressed are those of the authors and do not necessarily reflect those of the NHS, NIHR or the Department of Health.
