

eFigure. Time from Onset to Treatment Versus Age of Onset

Abbreviation: IVIg, intravenous immunoglobulins.

The two groups did not differ systematically in terms of either age of onset ($p=0.83$) or time from onset to treatment ($p=0.51$). The gray region covers onset ages from 55–80 and treatments undertaken within 20 months and represents a subset of 36 individuals treated with corticosteroids and 20 individuals treated with IVIg who are highly comparable in terms of these baseline factors.
